

A woman in a pink tutu is captured in a dynamic pose, spinning on a floral-patterned couch. Her hair is flying wildly, and the tutu is billowing out, creating a sense of motion. The background is a plain, light-colored wall.

Cloth

Hair

Lesson

11

and

soft bodies

# Lesson 08 Outline

- \* Problem definition and motivations
- \* Modeling deformable solids with mass-spring model
- \* Position based dynamics
- \* Modeling cloths with mass-spring model
- \* Modeling hair with mass-spring model
- \* Demos / tools / libs

# Simulation of Deformable Solids

- \* Lagrangian Mesh Based Methods
  - Continuum Mechanics Based Methods
  - Mass-Spring Systems
- \* Lagrangian Mesh Free Methods
  - Loosely Coupled Particle Systems
  - Smoothed Particle Hydrodynamics (SPH)
  - Mesh Free Methods for the solution of PDEs
- \* Reduced Deformation Models and Modal Analysis
- \* Eulerian and Semi-Lagrangian Methods
  - Fluids and Gases
  - Melting Objects

# Mass-spring

Model

A close-up photograph of a green metal coil spring, likely made of steel, set against a solid blue background. The spring is coiled in a helical pattern, with the coils overlapping and creating a sense of depth. The lighting highlights the metallic texture and the curves of the spring.

# Mass-spring Model

- \* Each deformable solid is modeled as a graph (mesh) of particles (with mass) connected with mass-less springs
- \* Particle Model
  - Each particle is defined at least by its Mass ( $m_i$ ), Position ( $p_i$ ), Velocity ( $v_i$ )
  - Additionally there can be force, acceleration, momentum ...
  - Usually particles can be incident to any number of springs
- \* Spring Model
  - Springs usually connects 2 particles and exerts force on them
  - Usually springs have non-zero rest length and some constant material properties

# Hook's Spring Model

- \* Hook's Law: Strain is directly proportional to stress
- \* Formally:  $f = -k_s x$ 
  - $x$  is the displacement of the end of the spring from its equilibrium position
  - $f$  is the restoring force exerted by the material
  - $k_s$  is a material constant called spring stiffness
- \* Using rest length and velocity damping
- \*  $f = - [k_s (|l| - l_0) + k_d (v_a - v_b) / |l|] (l / |l|)$ 
  - $k_d$  is damping factor

# Position based Dynamics

# Position based Dynamics

- ★ Traditional force based dynamics must solve ODE using some integration scheme. Using simple and fast explicit methods can lead simulation to inaccuracy and instability
- ★ This can be prevented by solving large systems of equations (using implicit methods) or
- ★ Using more geometric approach by directly modify positions into stable and more accurate states.
- ★ Such approach (position based dynamics) gives more control over animation and easily models constraints.

# Position based Dynamics

## \* Object Representation

- We represent dynamic object with a set  $N$  vertices
- Each vertex has: Mass ( $m_i$ ), Position ( $\rho_i$ ), velocity ( $v_i$ )

## \* Constraint Representation

- Let  $\rho = (\rho_1, \dots, \rho_N)$  be the generalized position
- The constraint is a functions  $C_j(\rho) = C_j(\rho_1, \dots, \rho_N): \mathbb{R}^{3N} \rightarrow \mathbb{R}$
- Cardinality  $m_j$  is the number of “used” parameters
- Stiffness parameter  $k_j \in \{0 \dots 1\}$  is a material property
- We define equality (bilateral) constraint as:  $C_j(\rho) = 0$
- We define inequality (unilateral) constraint as:  $C_j(\rho) \geq 0$

# PBD: Algorithm

- \* 1: forall vertices  $i$ : initialize  $\rho_i = \rho_i^0$ ;  $v_i = v_i^0$ ;  $w_i = 1/m_i$
- \* 2: loop
  - 3: forall vertices  $i$  do {  $v_i \leftarrow v_i + \Delta t w_i f_{\text{ext}}(x_i)$  }
  - 4: DampVelocities( $v_1, \dots, v_N$ )
  - 5: forall vertices  $i$  do {  $q_i \leftarrow \rho_i + \Delta t v_i$  }
  - 6: forall vertices  $i$  do { CreateCollisionConstraints( $x_i \rightarrow \rho_i$ ) }
  - 7: loop  $n_s$  times { ProjectConstraints( $C_1, \dots, C_{M+Q}, q_1, \dots, q_N$ ) }
  - 8: forall vertices  $i$  do {  $v_i \leftarrow (q_i - \rho_i)/\Delta t$ ;  $\rho_i \leftarrow q_i$ ; }
  - 9: VelocityUpdate( $v_1, \dots, v_N$ )
- \* 10: endloop

# PBD: Algorithm

- \* First all masses, positions and velocities are initialized to rest state
- \* With each simulation frame we do
  - First we modify velocities due to external forces (3:)
  - Next we add artificial damping to the system (4:)
  - Then we predict new positions ( $q_i$ ) with simple Euler step (5:)
  - Next we detect and construct all collision constraints (6:)
  - We apply “projection” several times on all constraints (7:)
  - We find correct velocities and set projected positions (8:)
  - We apply friction and restitution impulses on velocities (9:)

# PBD: Constraint Projection

- ★ Assuming constraint is violated ie.  $C(\rho) \neq 0$  ( $<0$ ) we must find correction  $\Delta\rho$  such that  $C(\rho + \Delta\rho) = 0$  ( $\geq 0$ )
- ★ By linearization we get:  $C(\rho + \Delta\rho) \approx C(\rho) + \nabla_{\rho} C(\rho) \cdot \Delta\rho$ 
  - To conserve both momentums correction must be along direction of constraint function gradient  $\nabla_{\rho} C(\rho)$  ie:
  - $\Delta\rho = \lambda \nabla_{\rho} C(\rho)$ ;  $\lambda$  (Lagrange multiplier) is a scalar
  - $\lambda = -C(\rho) / |\nabla_{\rho} C(\rho)|^2$
  - For i-th particle with mass  $m_i$  ( $w_i = 1/m_i$ )
  - $\Delta\rho_i = \lambda w_i \nabla_{\rho} C(\rho_1, \dots, \rho_N)$
  - $\lambda = -w_i C(\rho_1, \dots, \rho_N) / \sum_j w_j |\nabla_{\rho_j} C(\rho_1, \dots, \rho_N)|^2$

# PBD: Distance Constraint

- ★ Let  $C(\rho) = C(\rho_1, \rho_2) = |\rho_1 - \rho_2| - d = 0$ 
  - $\nabla_{\rho_1} C(\rho_1, \rho_2) = (\rho_1 - \rho_2) / |\rho_1 - \rho_2|$
  - $\nabla_{\rho_2} C(\rho_1, \rho_2) = (\rho_1 - \rho_2) / |\rho_1 - \rho_2|$
  - $\lambda = (|\rho_1 - \rho_2| - d) / w_1 + w_2$  where  $w_1 = 1/m_1$  and  $w_2 = 1/m_2$
  - $\Delta\rho_1 = (w_1 / (w_1 + w_2)) (|\rho_1 - \rho_2| - d) (\rho_1 - \rho_2) / |\rho_1 - \rho_2|$
  - $\Delta\rho_2 = (w_2 / (w_1 + w_2)) (|\rho_1 - \rho_2| - d) (\rho_1 - \rho_2) / |\rho_1 - \rho_2|$
- ★ For equality constraints we always do projection
- ★ For Inequality we project only when  $C(\rho) < 0$
- ★ Finally we multiply  $\Delta\rho$  with stiffness  $k$  ( $\Delta\rho k$ )
  - Due to iterations use  $k' = 1 - (1 - k)^{1/n_s}$ . Stiffness is applied linearly after  $n_s$  iterations

# PBD: Collisions

- ★ Given old position  $p_i$  and predicted position  $q_i$  we detect if a ray  $(p_i, q_i)$  enters some object. If yes we compute entry point  $q_c$  and collision normal  $n_c$
- ★ Next add collision constraint with stiffness  $k = 1$   
 $C(p) = (p - q_c) \cdot n_c \geq 0$  (ensures non-penetration)
  - When scene contains more dynamic bodies we must provide constraint from all bodies into one “scene” solver
  - For triangle meshes with face  $(p_1, p_2, p_3)$ :  $n_c = (p_2 - p_1) \times (p_3 - p_1)$
  - Collision constraint generation is done outside the solver loop, to speed up simulation. Artifacts are negligible

# PBD: Damping

- \* Velocities are damped
- \* for all vertices  $i$ 
  - $\Delta v_i = v_{cm} + \omega \times r_i - v_i$
  - $v_i \leftarrow v_i + k_d \Delta v_i$
- \* endfor
- \*  $\Delta v_i$  only damps local deviations
  - Here  $v_{cm} + \omega \times r_i$  is the velocity due to global body motion
- \* Global “body” variables
  - $\rho_{cm} = (\sum_i \rho_i m_i) / (\sum_i m_i)$
  - $v_{cm} = (\sum_i v_i m_i) / (\sum_i m_i)$
  - $L = \sum_i r_i \times (m_i v_i)$
  - $J = \sum_i (r_i^x) (r_i^x)^T m_i$
  - $\omega = J^{-1} L$
  - $r_i = \rho_{cm} - \rho_i$
  - $r_i^x$  is cross product matrix

# Position based Dynamics - Summary

- \* Control over explicit integration with no typical instability problems
- \* Positions of vertices and objects parts can directly be manipulated during the simulation
- \* Simple handling of general constraints in the position based setting
- \* The explicit position based solver is easy to understand and implement.

# Modeling Cloth

# Cloth: Representation

- ★ Cloth is represented with arbitrary manifold triangular mesh (no need for regular lattice)
- ★ Each mesh vertex become a simulation particle
- ★ Given cloth density and thickness we calculate mass of each triangle.
- ★ Mass of each particle is sum of  $1/3$  of the mass of each adjacent triangle.
- ★ Constraints are defined along edges and faces
- ★ Cloth tearing is performed on vertices with large deformations

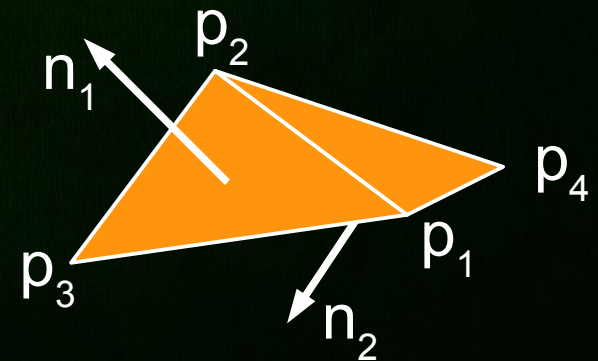

# Cloth: Constraints

## \* Stretching Constraints

- Along each mesh edge we define fixed stretching constraint as simple equality distance constraint (spring)
- $C_s(\rho_1, \rho_2) = |\rho_1 - \rho_2| - l_0$  where  $l_0$  is rest length
- Stiffness  $k_s$  is usually higher to overcome springiness

## \* Bending Constraints

- For each pair of adjacent triangles  $(\rho_1, \rho_3, \rho_2)$  and  $(\rho_1, \rho_2, \rho_4)$  we define a bending constraint
- $C_b(\rho_1, \rho_2, \rho_3, \rho_4) = \text{acos}(n_1, n_2) - \varphi_0$  where
  - $n_1 = ((\rho_2 - \rho_1) \times (\rho_3 - \rho_1)) / |(\rho_2 - \rho_1) \times (\rho_3 - \rho_1)|$
  - $n_2 = ((\rho_2 - \rho_1) \times (\rho_4 - \rho_1)) / |(\rho_2 - \rho_1) \times (\rho_4 - \rho_1)|$

# Cloth: Collisions and Tearing

- \* Inequality collision constraints is defined as
- \*  $C_b(q, \rho_1, \rho_2, \rho_3) = (q - \rho_1) \cdot n - h$ 
  - $q$  is collided point with face  $(\rho_1, \rho_2, \rho_3)$
  - $n$  is face normal
  - $h$  – distance to the face.
- \* Collision with rigid body exerts impulse  $m_i \rho_i / \Delta t$  at  $\rho_i$
- \* More involved self-collision detection must be done  
cloth becomes to be tangled

# Cloth: Overpressure and Tear

- \* Overpressure inside the closed mesh is modeled as
  - $C(\rho_1, \dots, \rho_N) = \sum_j (\rho_{j1} \times \rho_{j2}) \cdot \rho_{j3} - k_\rho V_0$
  - $\nabla_{\rho_1} C = \sum_j (\rho_{j2} \times \rho_{j3}) + \sum_j (\rho_{j3} \times \rho_{j1}) + \sum_j (\rho_{j1} \times \rho_{j2})$
- \* Cloth Tearing Process
  - Whenever the stretching of an edge exceeds a specified threshold value, we select one of the edge's adjacent vertices
  - We then put a split plane through that vertex perpendicular to the edge direction and split the vertex into 2 new vertices
  - All triangles above the split plane are assigned to the original vertex while all triangles below are assigned to the duplicate

# Cloth: Stiffness and Bending

$(k_s; k_b) = (1; 1)$

$(k_s; k_b) = (0.5; 1)$

$(k_s; k_b) = (0.01; 1)$

$(k_s; k_b) = (1; 0)$

$(k_s; k_b) = (0.5; 0)$

$(k_s; k_b) = (0.01; 0)$

# Cloth: Self Collisions and Balloons

# Cloth: Examples

A close-up, profile view of a woman's face and hair. The woman has long, wavy, light brown hair that is styled and voluminous. Her face is in profile, looking towards the right. She has dark, well-defined eyebrows, long eyelashes, and dark lipstick. The lighting is warm and soft, highlighting the texture of her hair and the contours of her face. On the left side of the image, there is a dark, semi-transparent rectangular overlay containing the text "Modeling Hair" in a white, sans-serif font. The word "Modeling" is smaller and positioned above the word "Hair", which is significantly larger and more prominent.

Modeling  
Hair

# Hair: Representation

- ★ Each hair strand is modeled as a set of vertices connected by edges into series of line segments
- ★ Each vertex is used as simulation particle
- ★ Given material density and strand thickness we can calculate volume/mass of each segment. Particle mass is average of incident edge masses
- ★ Strand constraints are applied along edges, additional (virtual) edges and newly created particles
- ★ Hair tearing is performed on vertices with large deformations

# Hair: Constraints

- \* We model Curly Hair and Straight Hair
- \* Stretching Constraints (springs)
  - Linear springs between every consecutive particle
- \* Bending Constraints (springs)
  - Linear springs between every other particle
  - The edge springs and bending springs together form triangles that implicitly represent the orientation of the hair
- \* Torsion Constraints (springs)
  - Twist is modeled by attaching torsion springs that connect each particle to a particle three particles away from it
- \* Altitude Constraints (springs)
  - See figure

## Point/Face Altitude Springs

(a) Spring has all non-negative barycentric weights

(b) Spring has negative barycentric weights

(c) Degenerate: all point/face springs have negative barycentric weights

## Edge/Edge Altitude Springs

(d) Spring has all non-negative barycentric weights

(e) Spring has negative barycentric weights

(f) Degenerate: all edge/edge springs have negative barycentric weights

# Hair: Altitude Springs

## \* Point/Face Altitude Springs

- Perpendicular to the face starting from the given point
- Length is  $l = 6V / |u \times v|$  where  $u$  and  $v$  are the vectors of the base triangle and  $V$  is the signed volume of the tetrahedron

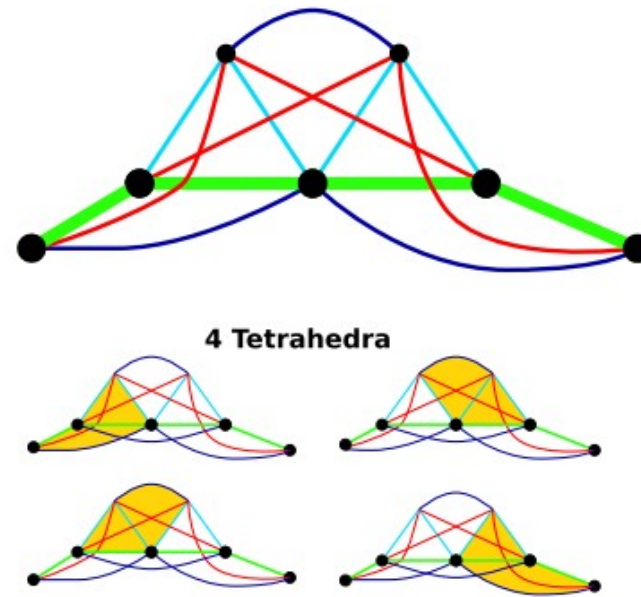

## \* Edge/Edge Altitude Springs

- Perpendicular to common spring and bending spring
- Length is  $l = 6V / |u \times v|$  where  $u$  and  $v$  are the stretch and bend spring and  $V$  is the signed volume of the tetrahedron
- For any tetrahedron, the edge/edge or point/face spring with minimal length is guaranteed to have all non-negative barycentric weights, preventing unbounded forces

**(a) Curly Hair Springs**

**(b) Straight Hair Springs**

**Figure 7:** *Straight and curly hair models using edge, bending, torsion, and altitude springs preserving the implied tetrahedra.*

**Torsion Spring Path Interrupted**

**Continuous Torsion Spring Path**

**Figure 8:** *Triangles define orientations for penalizing twist, and torsion springs “trace” a continuous path through the non-degenerate triangles—but they are blocked at straight hair segments (left). The subdivision and perturbation of our method removes degeneracies so the path becomes continuous (right).*

# Hair: Linear Strands

**Figure 9:** A simulation of 10,000 long straight hairs with 50 segments each (1,000,000 total particles) on a character shaking his head from side to side.

# Hair: Curly Strands

**Figure 14:** A simulation of 5,000 long curly hairs with 50 segments each (250,000 total particles) on a character spinning around from back to front.
